

## Insertion Sort

The algorithm is based on one assumption that a single element is always sorted.

Working principle

\* compare the element with adjacent element

Example

Input  $\rightarrow 1, 15, 9, 30, 10, 4, 35$

$\begin{array}{|c|c|c|c|c|c|} \hline 1 & 15 & 9 & 30 & 10 & 4 \\ \hline \end{array} \rightarrow \begin{array}{|c|c|c|c|c|c|} \hline 1 & 9 & 15 & 30 & 10 & 4 \\ \hline \end{array}$

$\begin{array}{|c|c|c|c|c|c|} \hline 1 & 9 & 15 & 30 & 10 & 4 \\ \hline \end{array} \rightarrow \begin{array}{|c|c|c|c|c|c|} \hline 1 & 9 & 15 & 30 & 10 & 4 \\ \hline \end{array}$

$\begin{array}{|c|c|c|c|c|c|} \hline 1 & 9 & 15 & 30 & 10 & 4 \\ \hline \end{array} \rightarrow \begin{array}{|c|c|c|c|c|c|} \hline 1 & 9 & 10 & 15 & 30 & 4 \\ \hline \end{array}$

$\begin{array}{|c|c|c|c|c|c|} \hline 1 & 9 & 10 & 15 & 30 & 4 \\ \hline \end{array} \rightarrow \begin{array}{|c|c|c|c|c|c|} \hline 1 & 4 & 9 & 10 & 15 & 30 \\ \hline \end{array}$

complexity

worst case  $-\Theta(n^2)$

Average case  $-\Theta(n^2)$

Best case  $-\Theta(n)$

for the best case array is already sorted hence only one time we have to check

# Optimization

Searching & swapping are two main function

- ① Optimising searching by using BST which reduce the search complexity from  $O(n)$  to  $O(\log n)$  for one element and for  $n$  element  $O(n \log n)$
- ② we can optimize the swapping by using doubly linked list. which will ~~req~~ reduce complexity of swapping  $n$  element from  $O(n)$  to  $O(1)$  as we can insert an element by changing pointers but searching remains  $O(n^2)$  as we cannot use binary search in link list. Thus over all complexity remains  $O(n^2)$
